

Name: Smoking Status

Short Description: Percentage of adults that currently smoke cigarettes (calculated as a crude prevalence).

Data Source(s):

- **Name:** The Centers for Disease Control and Prevention (CDC) Behavioral Risk Factor Surveillance System (BRFSS), accessed via the PLACES Project Data Portal
- **Link to Source:**
<https://chronicdata.cdc.gov/browse?category=500+Cities+%26+Places&sortBy=newest&utf8>

Year(s): 2018

Source Geographic Level: Zip Code Tabulation Area (ZCTA)

Stratification: Not available

Selection Rationale: Smoking (tobacco use disorder)¹ is the most common form of substance use so measuring cigarette smoking prevalence in a population is essential to understanding substance use prevalence. There is also a strong relationship between smoking and common mental disorders, as smoking is a frequent coping mechanism for distress.² Smoking is therefore both a direct and indirect measure of mental wellness in a community.

Strengths and Limitations:

- **Strengths:**
 - *[Importance]* Smoking is the most common form of substance use disorder, and is linked to several common mental disorders, making smoking essential to understanding the mental wellness of a population.
 - *[Equity]* This measure captures disparities experienced between population groups. While Black populations on the whole smoke fewer cigarettes than Hispanic and White populations, they are more likely to die of a smoking-related disease³ and are specifically targeted by tobacco companies.⁴

- [Relevance & Usability] By understanding the prevalence of cigarette smoking, users of the tool will be able to best target substance use interventions in a community.
 - [Feasibility] The data are easily downloadable from PLACES and maintained by the CDC Division of Population Health, Epidemiology and Surveillance Branch.
 - [Scientific Soundness] The methods used by the CDC to generate these small area estimates accounts for the associations between individual health outcomes, individual characteristics, and spatial contexts. CDC’s internal and external validation studies confirm strong consistency between small area estimates and direct BRFSS survey estimates at state and county levels.⁵
- **Limitations:**
 - [Relevance and Usability] This measure reports data only for cigarette smoking, not for other types of smoking, such as e-cigarettes, marijuana, or cigars.
 - [Relevance and Usability] This measure is a model-based estimate,⁶ so it may be difficult to interpret on its own.
 - [Scientific Soundness] This measure is self-reported and depends on the accuracy of the person surveyed.
 - [Scientific Soundness] Age-adjusted prevalence is not available at the census tract level, so these data are reported as a crude prevalence.
 - [Scientific Soundness] These data reflect only “current” smoking, rather than lifetime prevalence (although “current smokers” are required to have smoked at least 100 cigarettes in their lifetime to be counted in this measure).⁴

Calculation:

$$\text{Smoking} = \frac{\text{Respondents aged } \geq 18 \text{ years who report that they are current cigarette smokers}^*}{\text{Respondents aged } \geq 18 \text{ years who report information about cigarette smoking}^{**}} \times 100\%$$

*Where current cigarette smokers are defined as having smoked ≥ 100 cigarettes in their lifetime and currently smoke every day or some days. This does not include e-cigarette smokers.⁷

** Denominator excludes those who refused to answer, had a missing answer, or answered “don’t know/not sure.”⁸

Note - BRFSS estimates the crude prevalence based on self-reports using small area estimation and multilevel regression and poststratification, which links geocoded health surveys and high spatial resolution population demographic and socioeconomic data.⁹
